Philosophical Inquiries

concerning the Refraction of Luminous Rays

Read before the Society on the 14th day of November, 1684

An experiment was made in a darkened chamber, where a narrow beam entered through a slit and fell upon a triangular glass. The image upon the farther paper was observed to be neither circular nor still, but stretched according to the inclination of the glass. The figures 3, 4, 5, 7, and 9 in this sentence demonstrate old-style numerals.

From repeated trials it appeared that the several rays did not bend in equal measure. The circumstance was therefore recorded apart from the conjecture: first the position of the apparatus, then the distance to the receiving sheet, and only afterward the proposed account of the effect.

The long *s* in *obſerved* is explicit Unicode; the font's Historic feature supplies several others.

Observation I

The old-style figures, restrained ink color, narrow measure, broad outer margin, spaced small capitals, marginal note, and printer's rules are separate controls. Remove any one of them to judge its contribution rather than treating "vintage" as a single indivisible style.

Finis.
